Observed diversity relative to its neutral expectation, $\delta = \pi / 4\mu N_c$
Multiplicative bound, $V_{A,\delta} = \ln(1/\delta)/4\kappa_{max}$: the least V_A that could explain δ
Small-variance ceiling, $V_{A,max} = (1-\delta)/4\kappa\delta$, where it holds
Multiplicative bound with linkage, one line per mapped population
Measured $\hat{V}_A$ at observed δ: random mating
Measured $\hat{V}_A$ at observed δ: social monogamy
Each population's test: from $\hat{V}_A$ to the least V_A that could explain its δ, without and with linkage
